# Memory Management

# Table of Content

- Logical versus Physical Address Space.
- Swapping.
- Contiguous Allocation.
- Paging.
- Segmentation.
- Segmentation with Paging.

# **LOGICAL VS PHYSICAL ADDRESS SPACE**

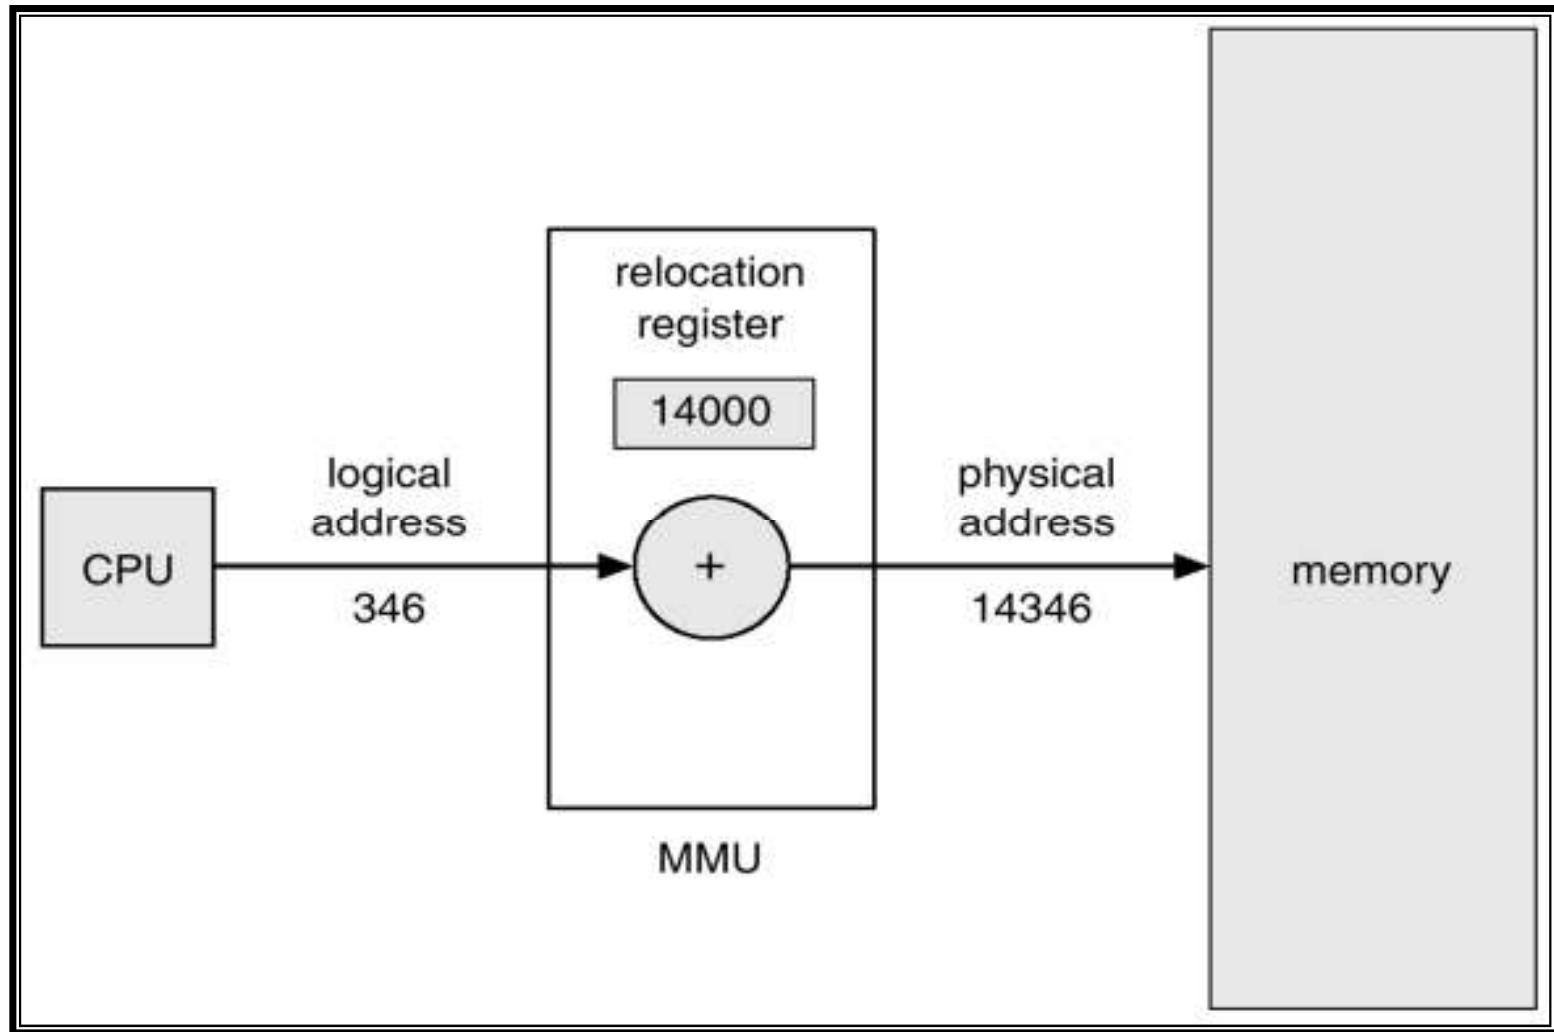

# Logical vs. Physical Address Space

- The concept of a logical *address space* that is bound to a separate *physical address space* is central to proper memory management.
  - *Logical address* – generated by the CPU; also referred to as *virtual address*.
  - *Physical address* – address seen by the memory unit.
- Logical and physical addresses are the same in compile-time and load-time address-binding schemes; logical (virtual) and physical addresses differ in execution-time address-binding scheme.

# Memory-Management Unit (MMU)

- Hardware device that maps logical (virtual) to physical address.
- In MMU scheme, the value in the relocation register (base register) is added to every address generated by a user process at the time it is sent to memory.
- The user program deals with *logical* addresses; it never sees the *real* physical addresses.

# Dynamic relocation using a relocation register

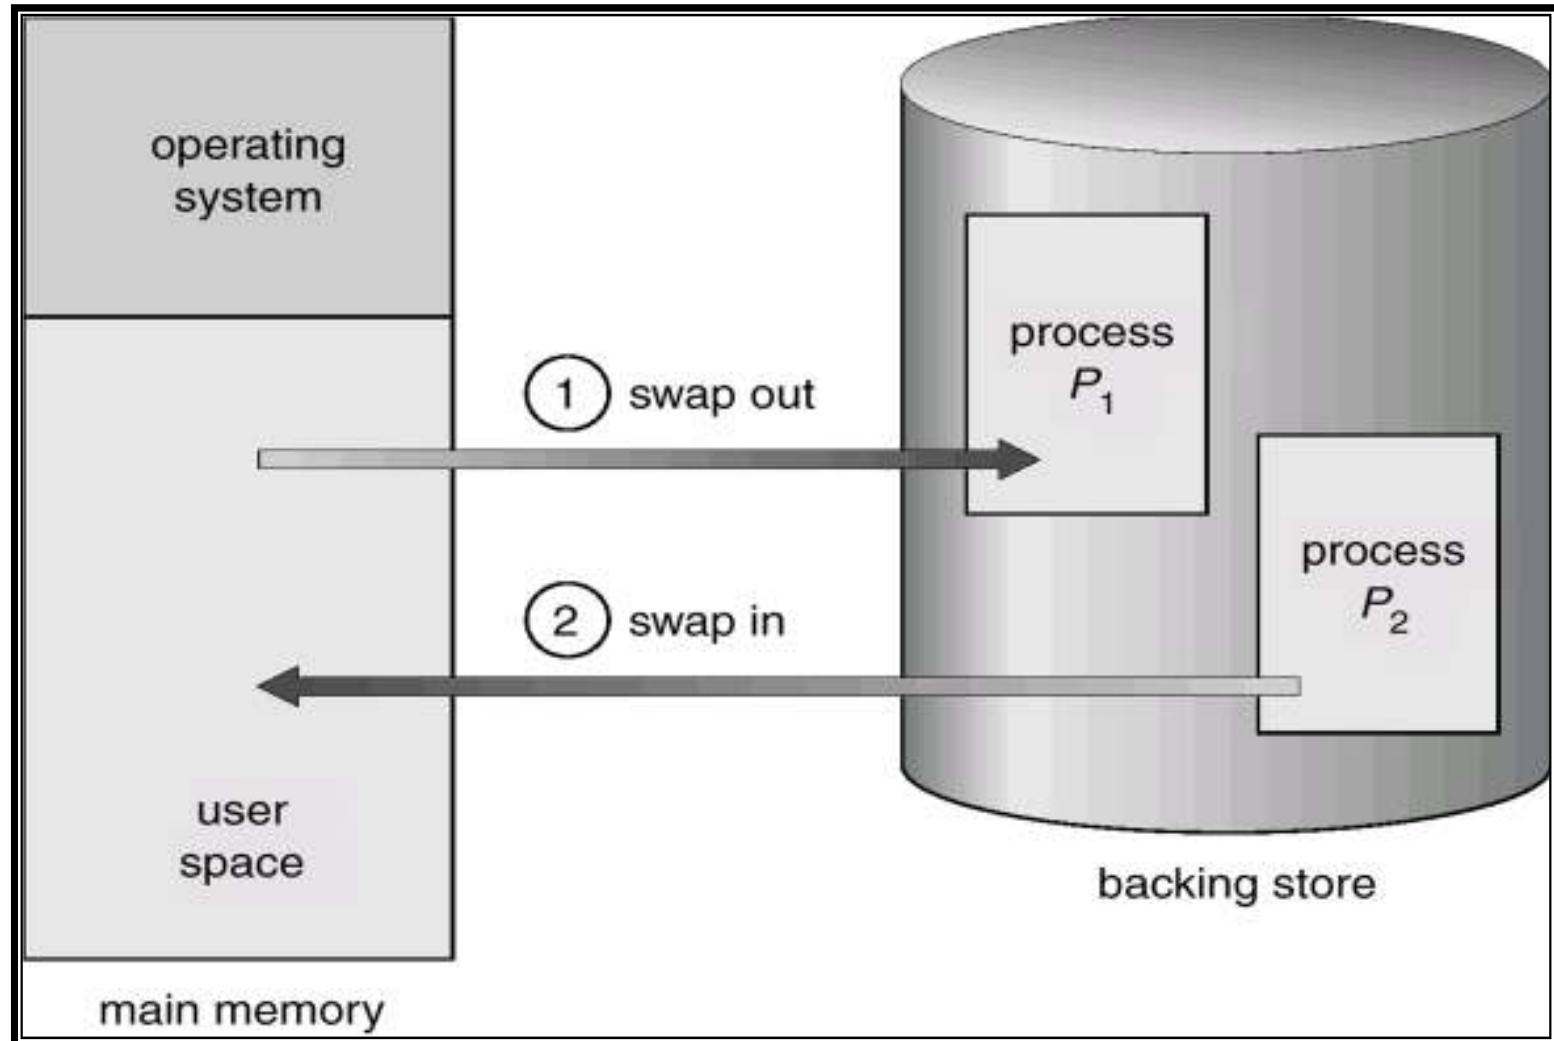

# **SWAPPING**

# Swapping

- A process can be *swapped* temporarily out of memory to a Backing store, and then brought back into memory for continued execution.
- Backing store – fast disk large enough to accommodate copies of all memory images for all users; must provide direct access to these memory images.
- *Roll out, roll in* – swapping variant used for priority-based scheduling algorithms; lower-priority process is swapped out so higher-priority process can be loaded and executed.
- Major part of swap time is transfer time; total transfer time is directly proportional to the *amount* of memory swapped.
- Modified versions of swapping are found on many systems, i.e., UNIX, Linux, and Windows.

# Schematic View of Swapping

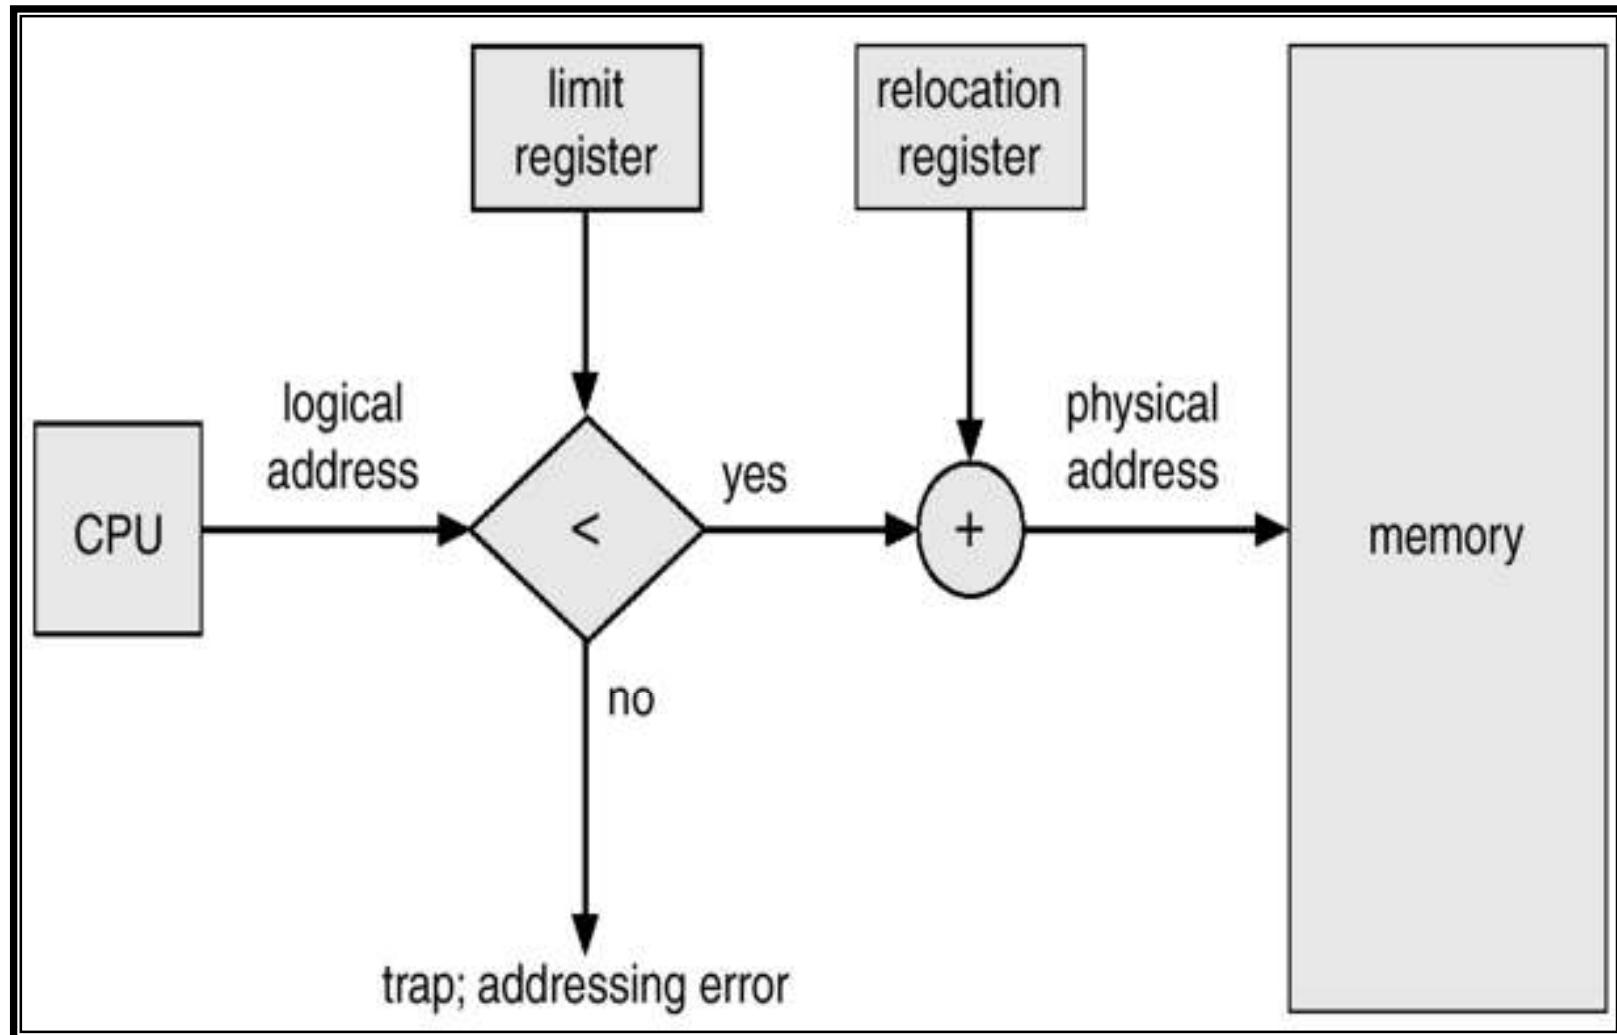

# **CONTIGUOUS ALLOCATION**

# Contiguous Allocation

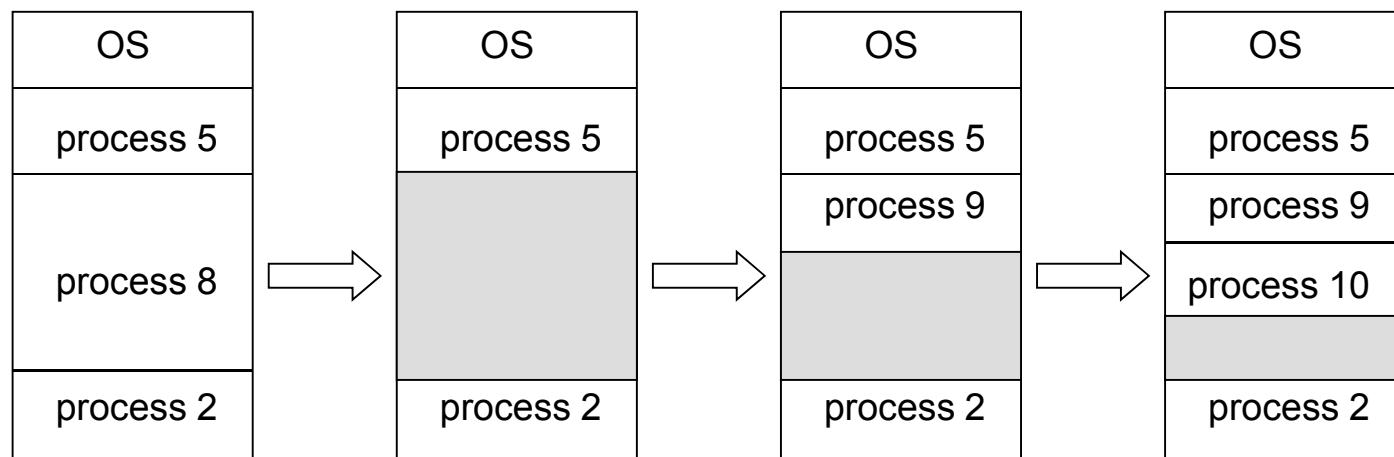

- Main memory usually into two partitions:
  - Resident operating system, usually held in low memory with interrupt vector.
  - User processes then held in high memory.
- Single-partition allocation
  - Relocation-register scheme used to protect user processes from each other, and from changing operating-system code and data.
  - Relocation register contains value of smallest physical address; limit register contains range of logical addresses.

# Hardware Support for Relocation and Limit Registers

# Contiguous Allocation (Cont.)

- Multiple-partition allocation
  - *Hole* – block of available memory; holes of various size are scattered throughout memory.
  - When a process arrives, it is allocated memory from a hole large enough to accommodate it.
  - Operating system maintains information about:
    - a) **allocated partitions**
    - b) **free partitions** (hole)

# Dynamic Storage-Allocation Problem

How to satisfy a request of size  $n$  from a list of free holes.

- **First-fit:** Allocate the *first* hole that is big enough.
- **Best-fit:** Allocate the *smallest* hole that is big enough; must search entire list, unless ordered by size.  
Produces the smallest leftover hole.
- **Worst-fit:** Allocate the *largest* hole; must also search entire list. Produces the largest leftover hole.

First-fit and best-fit better than worst-fit in terms of speed and storage utilization.

# Fragmentation

- **External Fragmentation** – total memory space exists to satisfy a request, but it is not contiguous.
- **Internal Fragmentation** – allocated memory may be slightly larger than requested memory; this size difference is memory internal to a partition, but not being used.
- Reduce external fragmentation by compaction

# PAGING

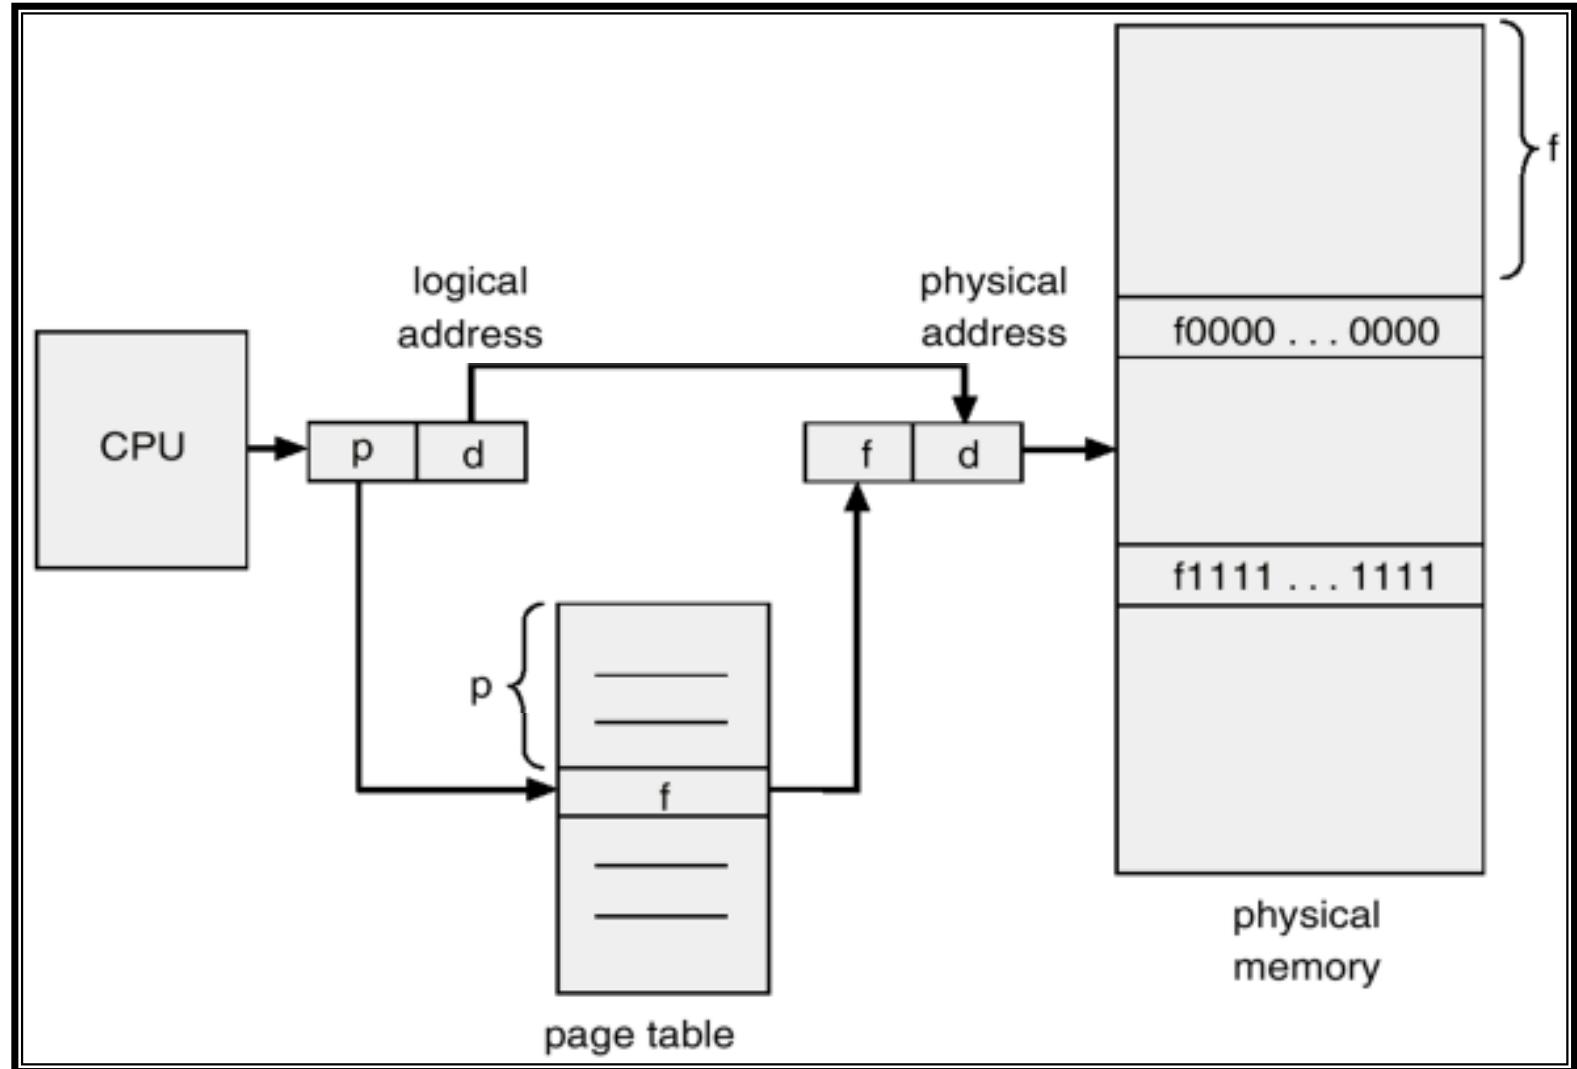

# Paging

- Logical address space of a process can be noncontiguous; process is allocated physical memory whenever the latter is available.
- Divide physical memory into fixed-sized blocks called **frames** (size is power of 2, between 512 bytes and 8192 bytes).
- Divide logical memory into blocks of same size called **pages**.
- Keep track of all free frames.
- To run a program of size  $n$  pages, need to find  $n$  free frames and load program.
- Set up a page table to translate logical to physical addresses.
- *Internal fragmentation.*

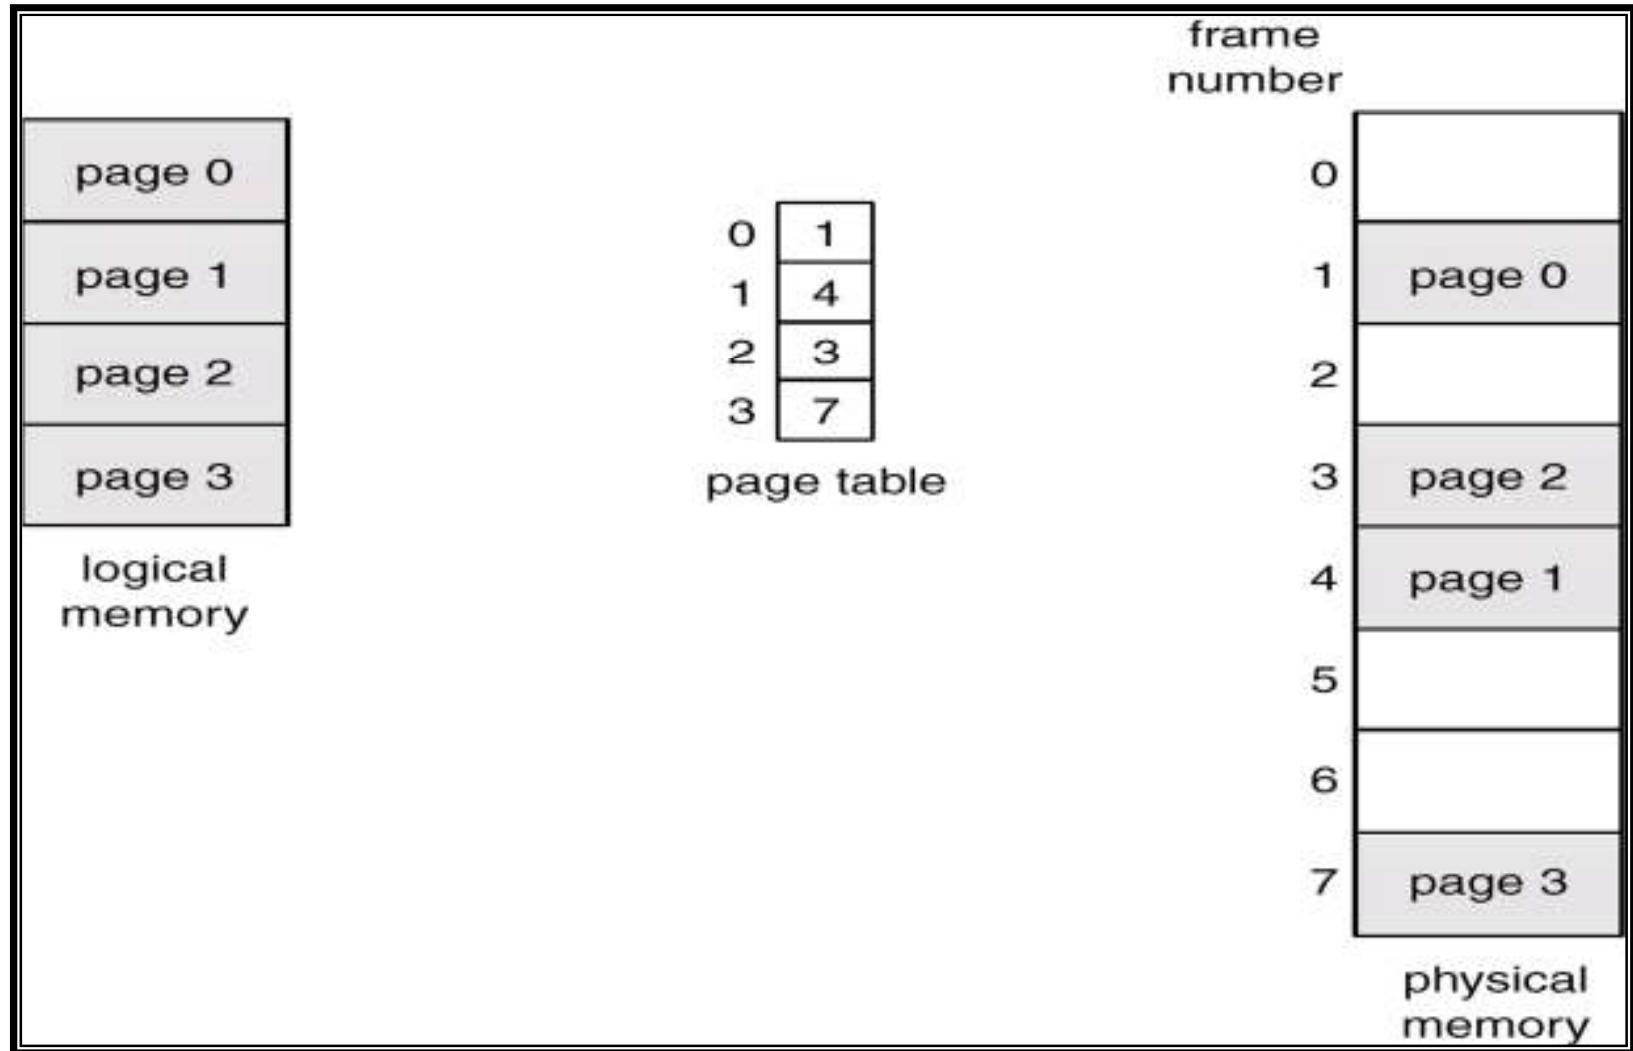

# Address Translation Scheme

- Address generated by CPU is divided into:
  - *Page number ( $p$ )* – used as an index into a *page table* which contains base address of each page in physical memory.
  - *Page offset ( $d$ )* – combined with base address to define the physical memory address that is sent to the memory unit.

# Address Translation Architecture

# Paging Example

# Paging Example

# Free Frames

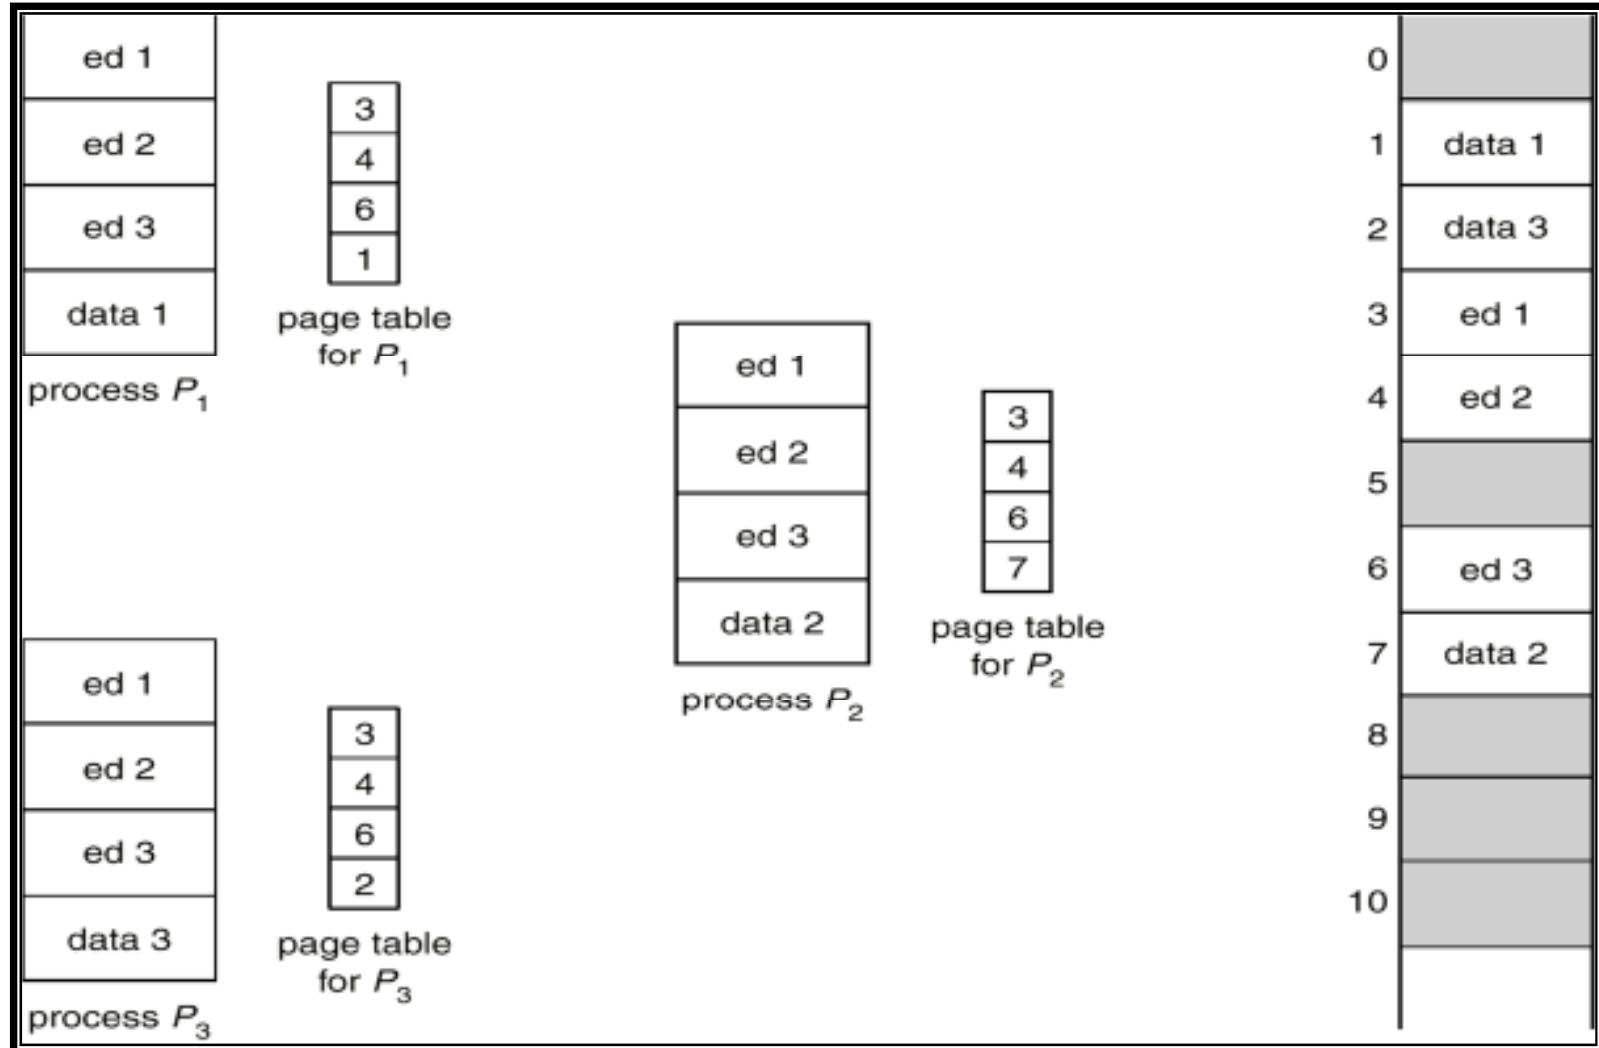

Before allocation

After allocation

# Shared Pages

- Shared code
  - One copy of read-only (reentrant) code shared among processes (i.e., text editors, compilers, window systems).
  - Shared code must appear in same location in the logical address space of all processes.

# Shared Pages Example

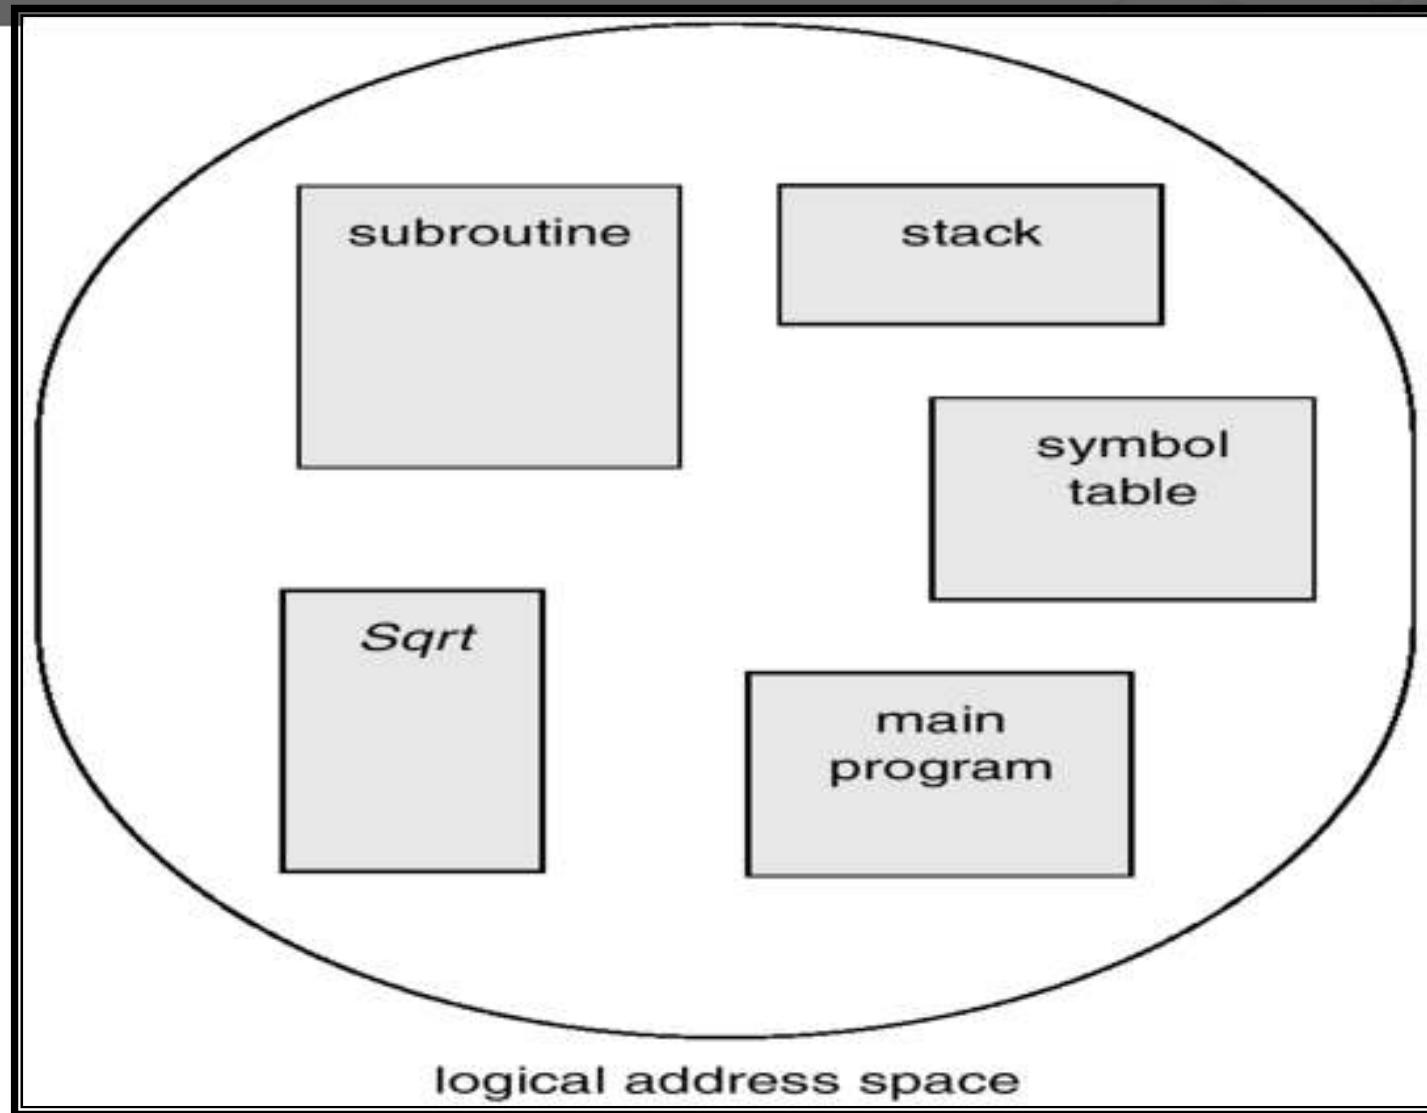

# **SEGMENTATION**

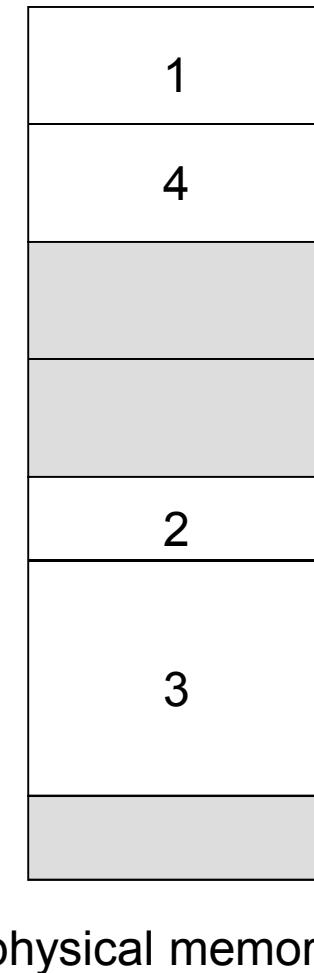

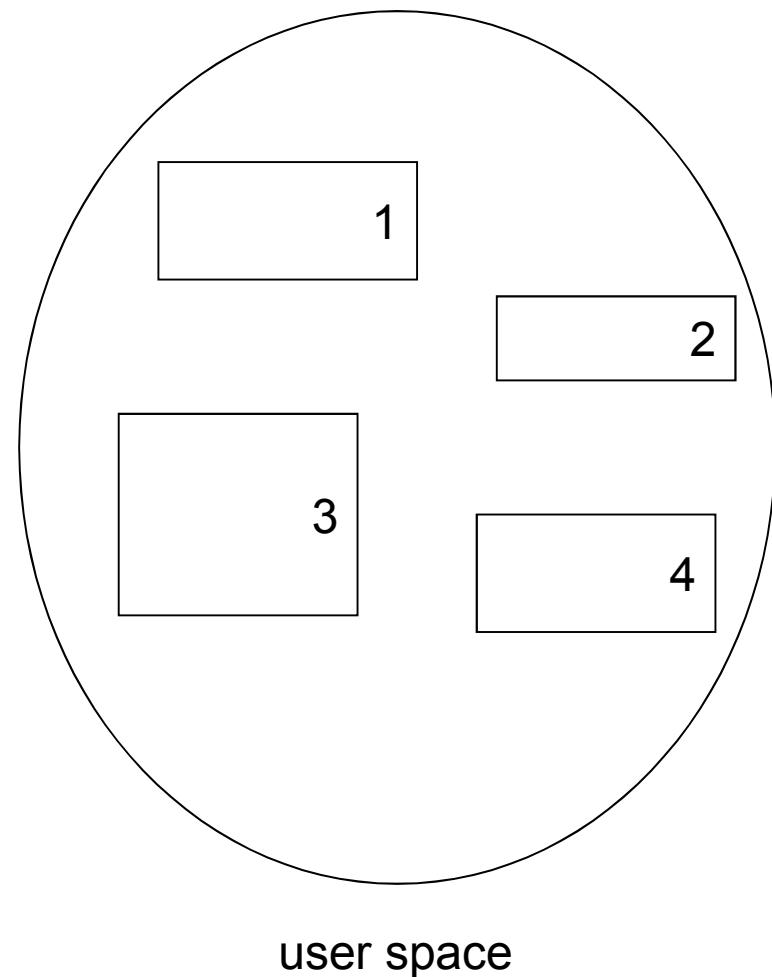

# Segmentation

- Memory-management scheme that supports user view of memory.
- A program is a collection of segments. A segment is a logical unit such as:
  - main program,
  - procedure,
  - function,
  - method,
  - common block,
  - stack,
  - symbol table, arrays

# User's View of a Program

# Logical View of Segmentation

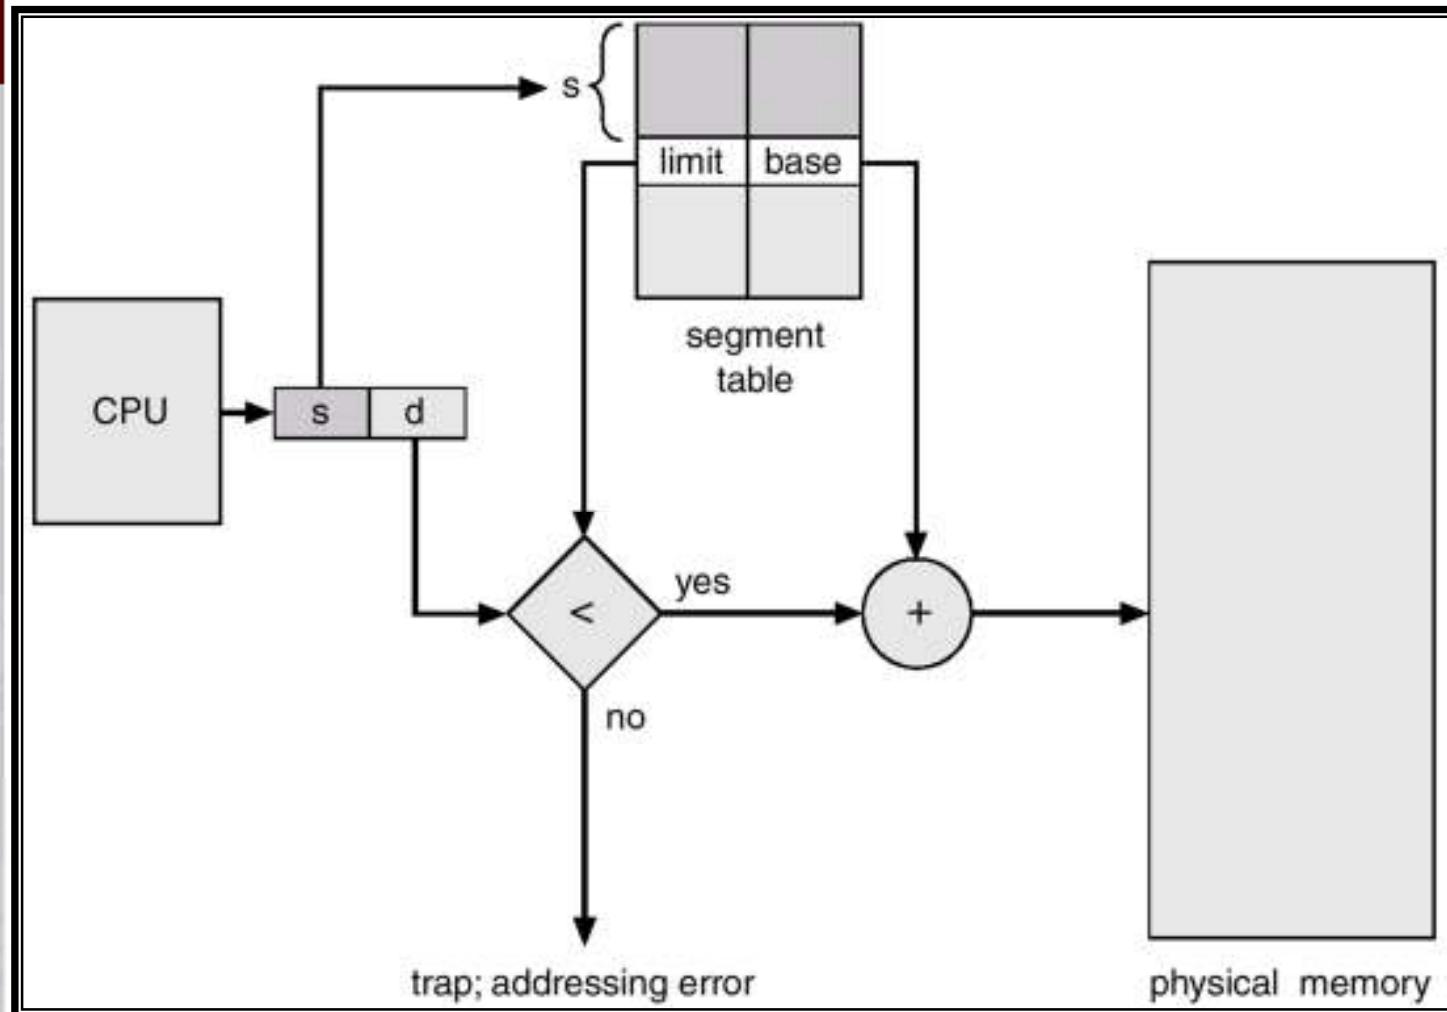

# Segmentation Architecture

- Logical address consists of a two tuple:  
 $\langle \text{segment-number}, \text{offset} \rangle,$
- *Segment table* – maps two-dimensional physical addresses; each table entry has:
  - base – contains the starting physical address where the segments reside in memory.
  - *limit* – specifies the length of the segment.

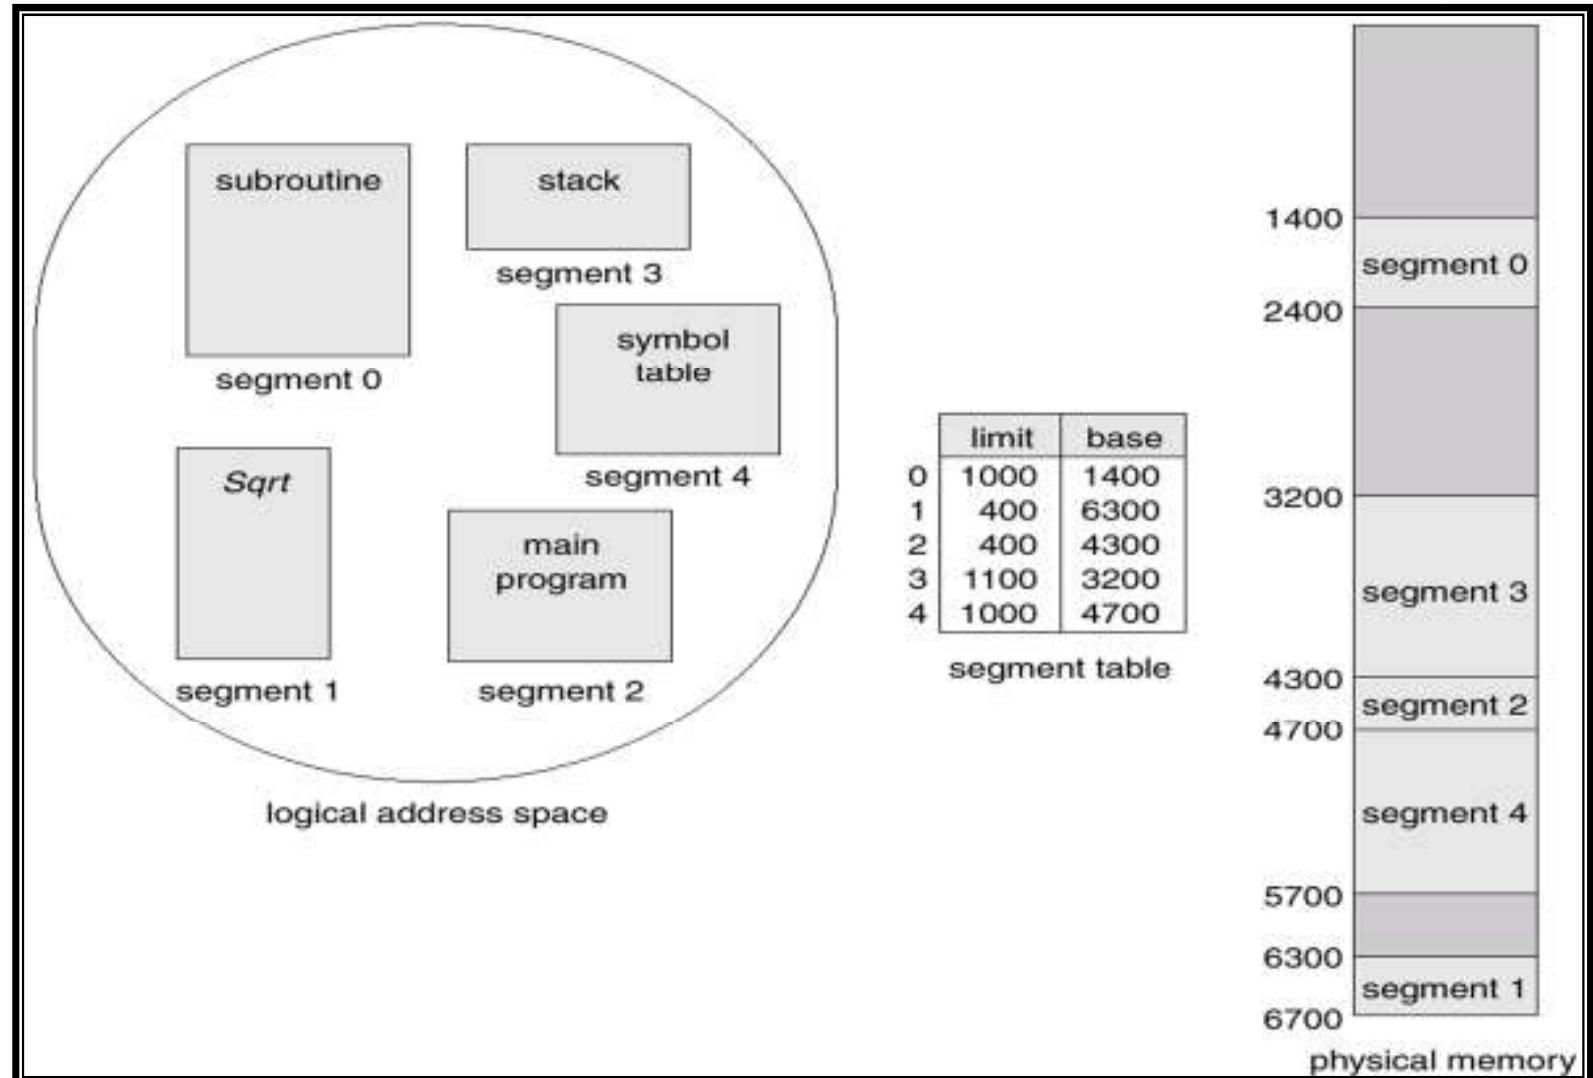

# Segmentation Architecture (Cont.)

- Relocation.
  - dynamic
  - by segment table
- Sharing.
  - shared segments
  - same segment number
- Allocation.
  - first fit/best fit
  - external fragmentation

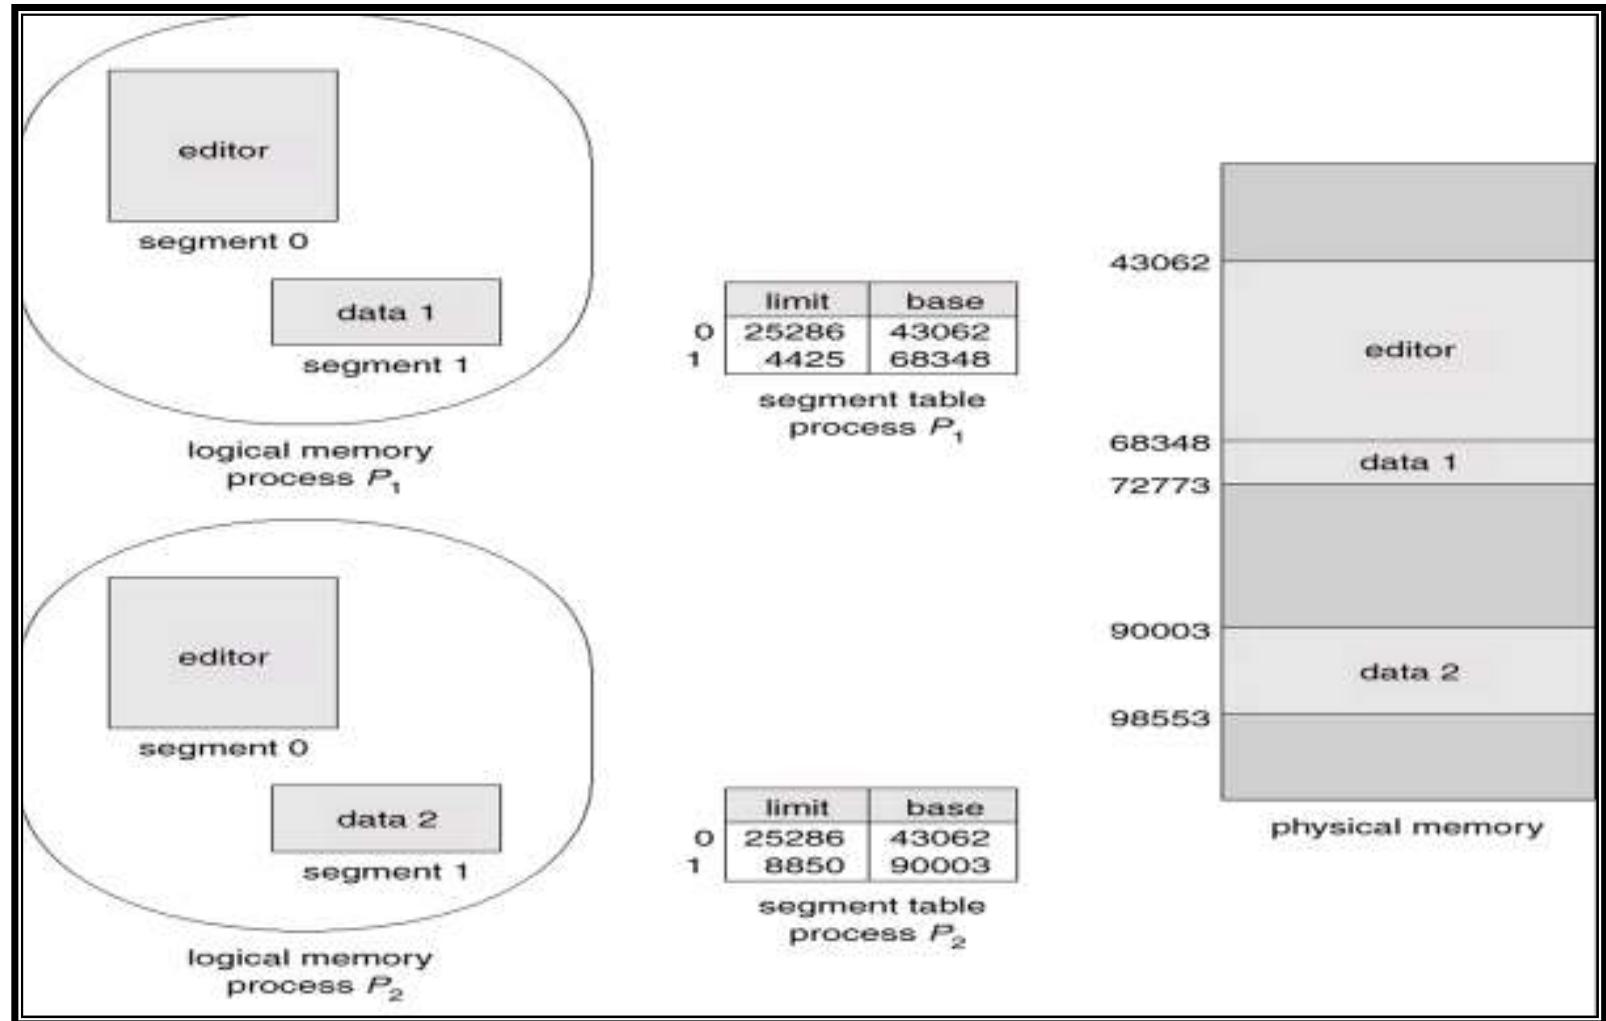

# Segmentation Hardware

# Example of Segmentation

# Sharing of Segments

# **SEGMENTATION WITH PAGING**

# Segmentation with Paging – MULTICS

- The MULTICS system solved problems of external fragmentation and lengthy search times by paging the segments.
- Solution differs from pure segmentation in that the segment-table entry contains not the base address of the segment, but rather the base address of a *page table* for this segment.
